# IMAGING ATMOSPHERIC CHERENKOV TELESCOPES

## How do they work?

Credit: CTA Consortium

They use the earth's **atmosphere** as a **calorimeter**:

1. A gamma or cosmic ray initiates a **particle cascades** in the atmosphere
2. **Secondary charged particles** traveling in the atmosphere will produce **Cherenkov light**
3. This Cherenkov light is ultimately measured by telescope with **fast** and **low-level sensors**

Energy range: 30 GeV – above 50 TeV

### Abstract

Long-duration  $\gamma$ -ray bursts (GRBs) are the most luminous sources of electromagnetic radiation known in the Universe. They arise from outflows of plasma with velocities near the speed of light that are ejected by newly formed neutron stars or black holes (of stellar mass) at cosmological distances<sup>1,2</sup>. Prompt flashes of megaelectronvolt-energy  $\gamma$ -rays are followed by a longer-lasting afterglow emission in a wide range of energies (from radio waves to gigaelectronvolt  $\gamma$ -rays), which originates from synchrotron radiation generated by energetic electrons in the accompanying shock waves<sup>3,4</sup>. Although emission of  $\gamma$ -rays at even higher (teraelectronvolt) energies by other radiation mechanisms has been theoretically predicted<sup>5,6,7,8</sup>, it has not been previously detected<sup>7,8</sup>. Here we report observations of teraelectronvolt emission from the  $\gamma$ -ray burst GRB 190114C.  $\gamma$ -rays were observed in the energy range 0.2–1 teraelectronvolt from about one minute after the burst (at more than 50 standard deviations in the first 20 minutes), revealing a distinct emission component of the afterglow with power comparable to that of the synchrotron component. The observed similarity in the radiated power and temporal behaviour of the teraelectronvolt and X-ray bands points to processes such as inverse Compton upscattering as the mechanism of the teraelectronvolt emission<sup>9,10,11</sup>. By contrast, processes such as

# Q.G. EFFECTS IN GRB 190114C

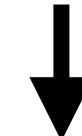

$$\Delta t = s_{\pm} \frac{n+1}{2} D_n(z) \left( \frac{E}{E_{\text{QG},n}} \right)^n$$

Photon energy  
at the detector

$$D_n(z) = \frac{1}{H_0} \int_0^z \frac{(1+\zeta)^n}{\sqrt{\Omega_\Lambda + (1+\zeta)^3 \Omega_m}} d\zeta$$

$$z = 0.42, \quad H_0 = 70 \text{ km s}^{-1} \text{ Mpc}^{-1}, \quad \Omega_\Lambda = 0.7, \quad \Omega_m = 0.3$$

$$\Delta t(E, \eta_1) = \eta_1 \cdot 17 \text{ s/TeV} \cdot E$$

$$\Delta t(E, \eta_2) = \eta_2 \cdot 25 \text{ s/TeV}^2 \cdot E^2$$

Assuming  $\eta_n = 1$  a 1 TeV gamma should have a **time delay** of

- **17 seconds** ( $n=1$ )
- **25 seconds** ( $n=2$ )

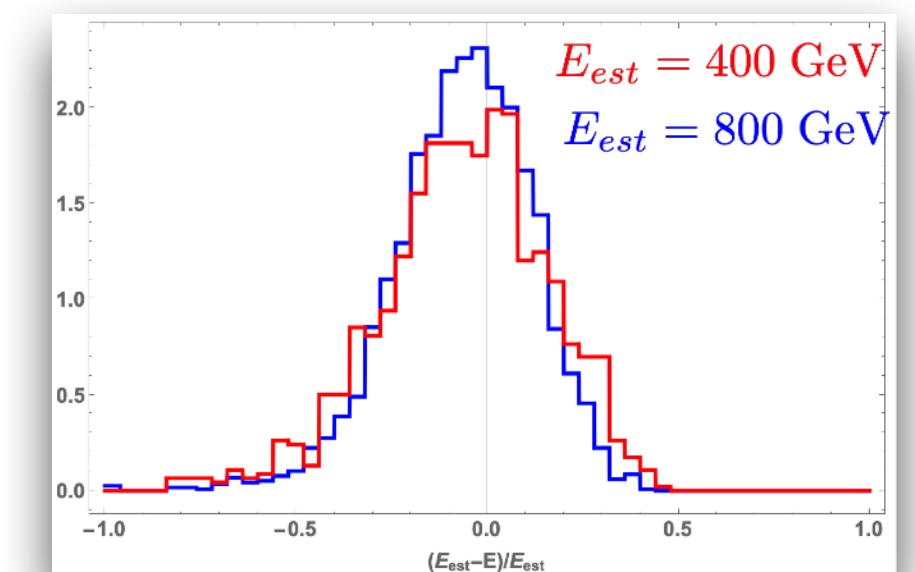

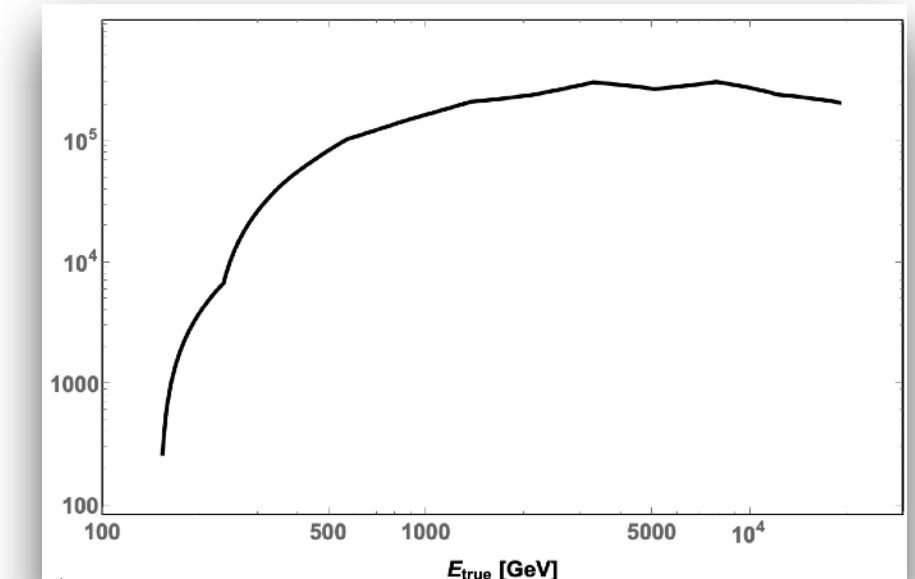

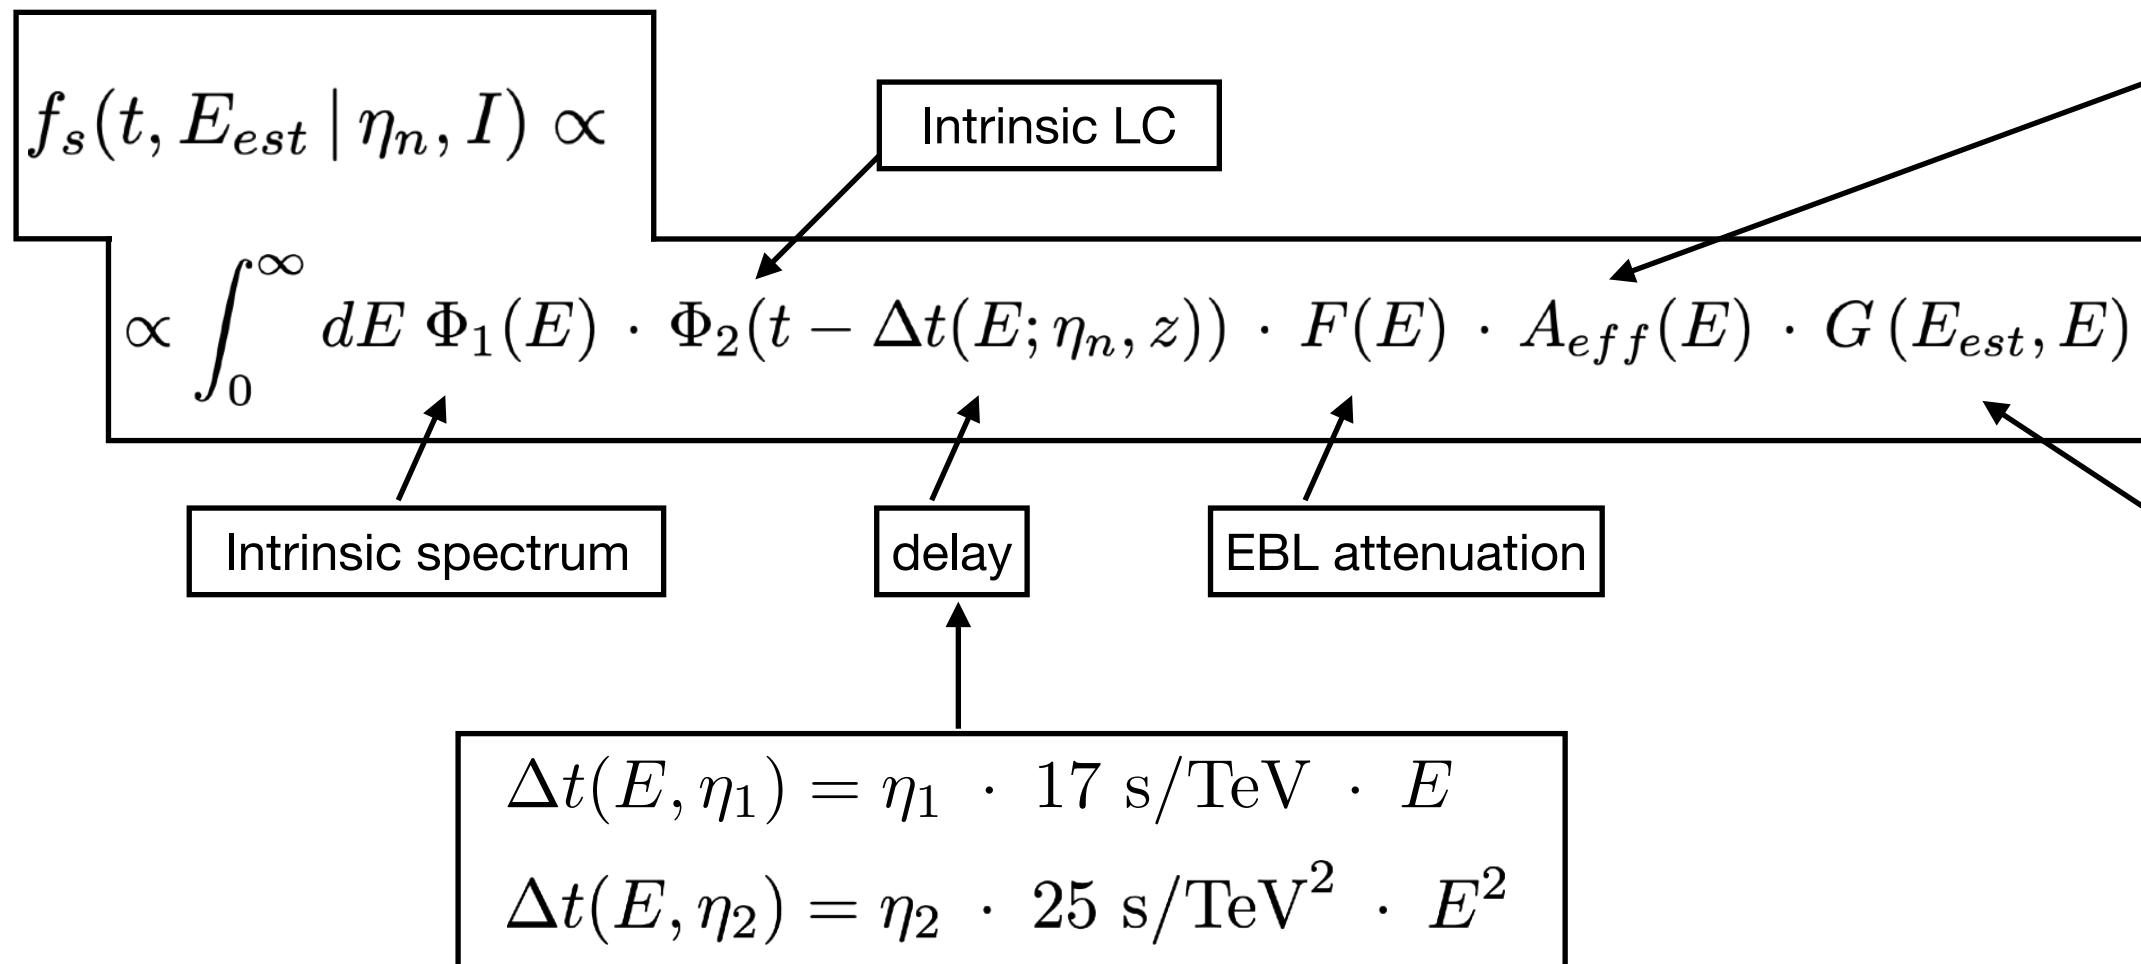

Where we have defined  $\eta$  as the **ratio** between the **Planck energy** and the **Q.G. energy scale**

$$\eta_1 = s_{\pm} \cdot E_{\text{Pl}} / E_{\text{QG},1} \quad \eta_2 = 10^{-16} \cdot s_{\pm} \cdot E_{\text{Pl}}^2 / E_{\text{QG},2}^2$$

# LIKELIHOOD ANALYSIS

## Likelihood

P.D.F. of detecting a **signal** event with a given estimated **energy** and arrival **time**

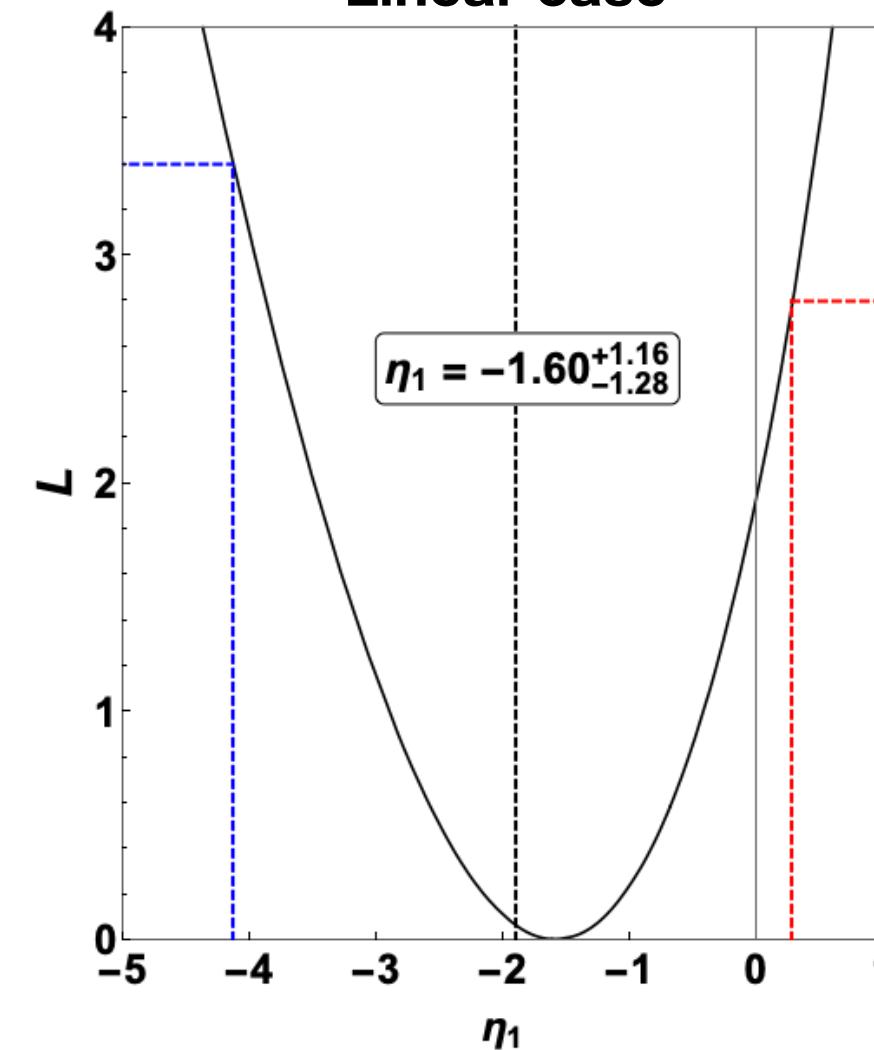

$$\mathcal{L}(\eta_n, I) = \prod_i^{N_{on}} \left( \frac{N_{on} - N_{off}}{N_{on}} \cdot f_s(t_i, E_i | \eta_n, I) + \frac{N_{off}}{N_{on}} \cdot f_b(t_i, E_i) \right) \cdot P(I)$$

P.D.F. of detecting a **background** event with a given estimated **energy** and arrival **time**

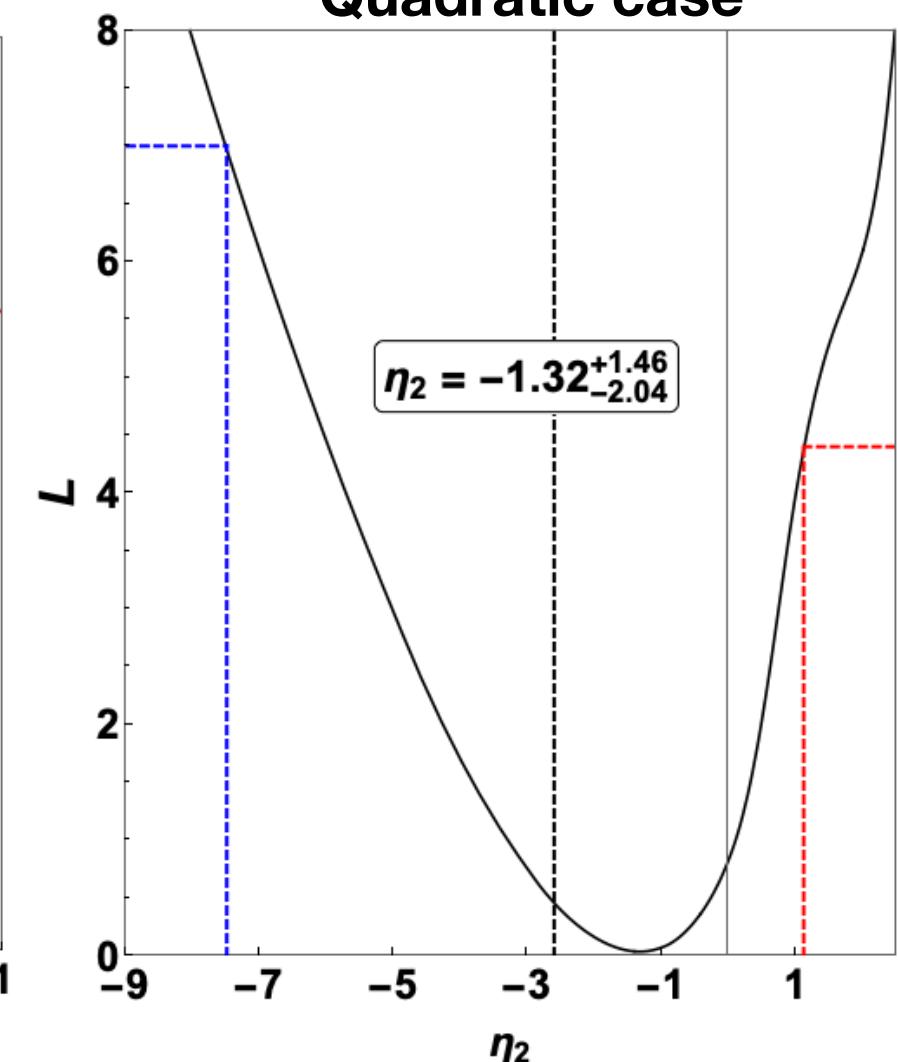

$$P(I) = \mathcal{N}(\beta | 1.51, 0.04) \cdot \mathcal{N}(\alpha | 2.5, 0.2)$$

## Likelihood profile

### Linear case

### Quadratic case

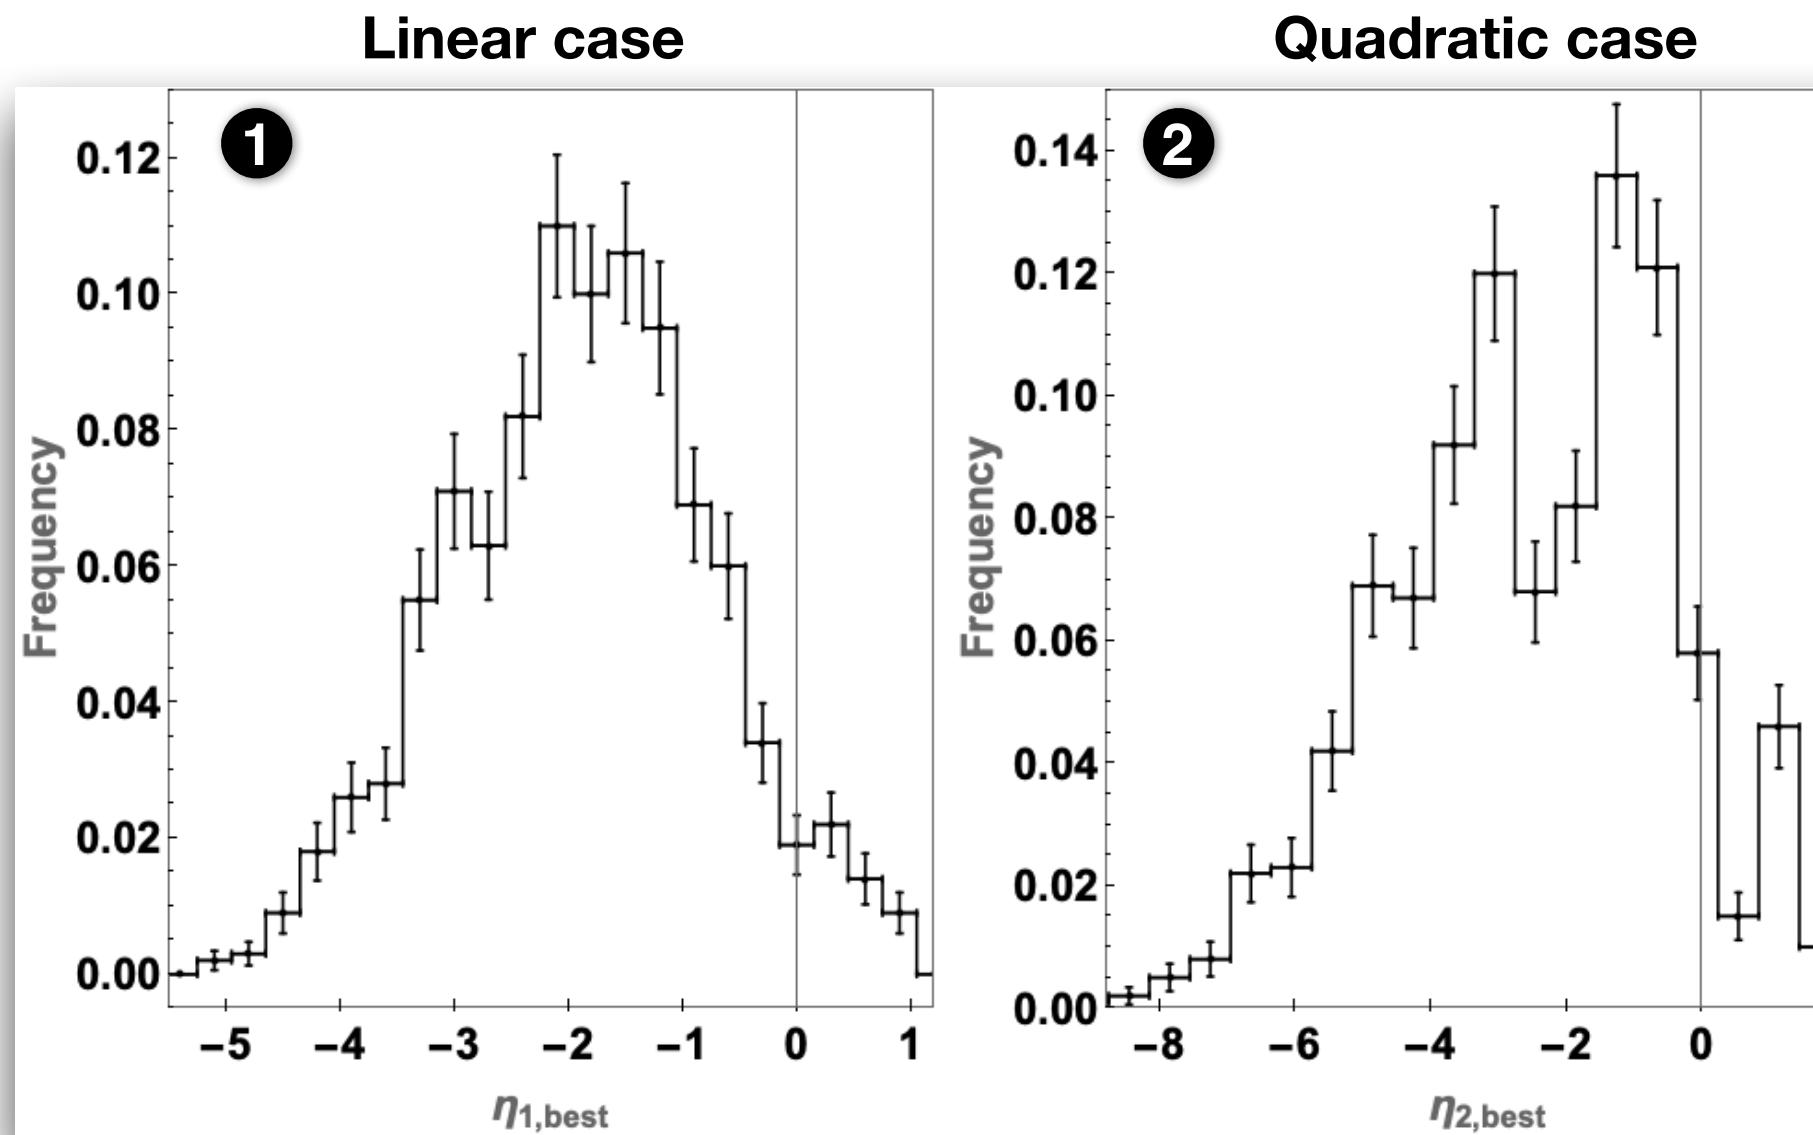

95% **LL** and **UL** thresholds are obtained from MCs

# LIKELIHOOD ANALYSIS

Is our **intrinsic** model compatible with the **null hypothesis**?

MC data sets is generated by **reshuffling + bootstrapping** the **real data set**, so that any **Q.G. effect**, if presents, is **destroyed** but **temporal and energy distribution** are **preserved**

① BIAS =  $-1.9$

② BIAS =  $-2.6$

- The **likelihood** is slightly shifted toward negative values (**superluminal scenario**)
- This also shows that our data are **compatible** with the null hypothesis

# RESULTS

From the GRB 190114C data we got the following 95% lower limits on the Q.G. energy scale

	superl.	subl.
$E_{\text{QG},1} [10^{19} \text{ GeV}]$	0.55	0.58
$E_{\text{QG},2} [10^{10} \text{ GeV}]$	5.6	6.3

95% lower limit on the Q.G. energy scale for  
← linear scenario  
← quadratic scenario

$$E_{Pl} \sim 1.2 \cdot 10^{19} \text{ GeV}$$

# CONCLUSIONS

- From the **300 GeV - 2 TeV** gamma-ray photons observed from GRB 190114C, we performed a **likelihood analysis** making a set of **conservative assumptions**:
  - Intrinsic **Light Curve** derived from **data** and from **theoretical models**
  - Intrinsic smooth **power-law spectrum** independent from time
  - **Q.G.** effects described by a **model with parameter  $\eta_n$**
- The values of  $\eta_1$  and  $\eta_2$  obtained from the **likelihood maximization** are **compatible at 1 sigma** with the null hypothesis: **no Q.G. effect**
- We derived at **95%** confidence level the following **lower limits** for the **quantum-gravity energy scale**:

	superluminal	subluminal
$E_{\text{QG},1} \text{ [GeV]}$	$> 0.55 \cdot 10^{19}$	$> 0.58 \cdot 10^{19}$
$E_{\text{QG},2} \text{ [GeV]}$	$> 5.6 \cdot 10^{10}$	$> 6.3 \cdot 10^{10}$

# THANK YOU FOR YOUR ATTENTION!

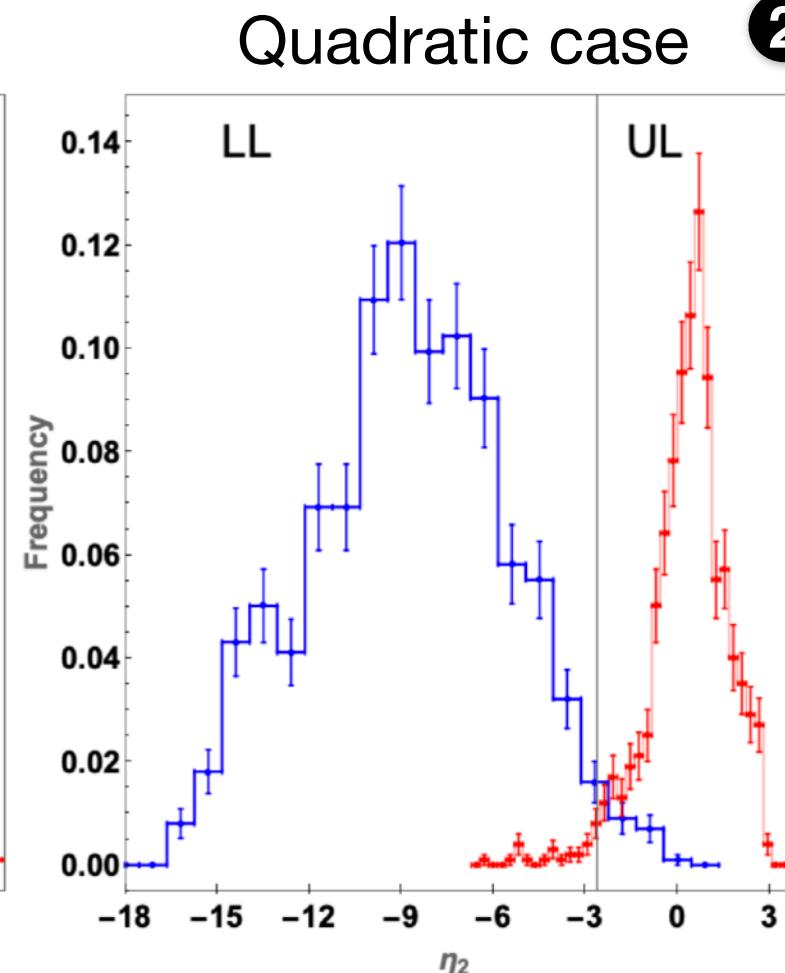

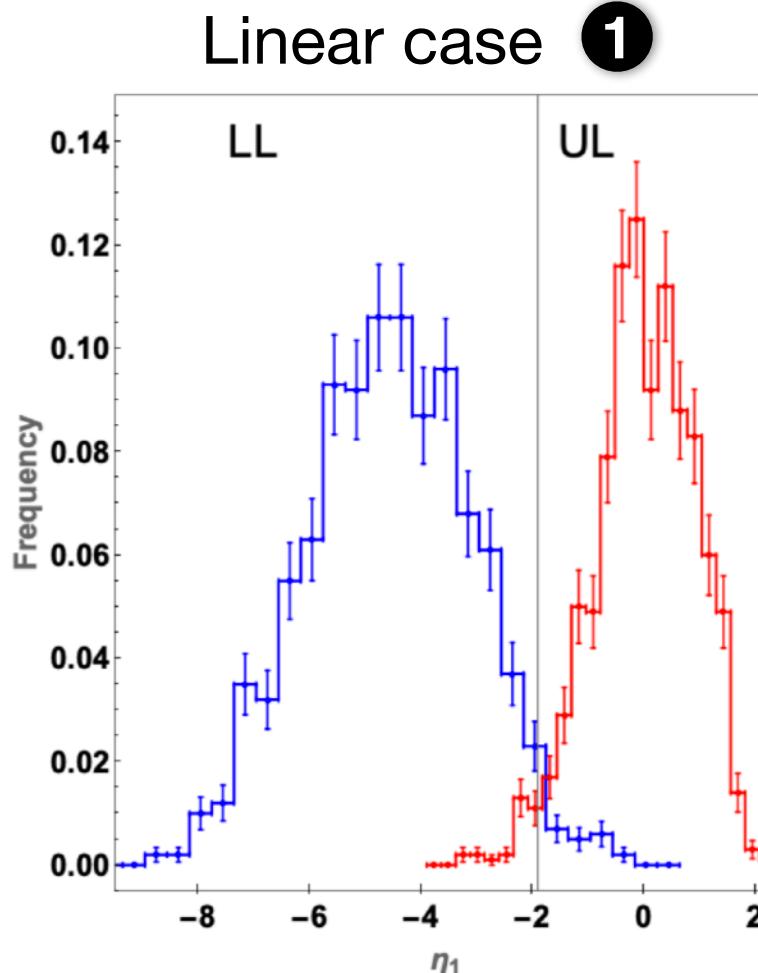

# BACKUP SILDE I

## Calibration of lower (**LLs**) and upper (**ULs**) limits using MC simulations:

For each **MC simulation** we compute the **LLs** and **ULs** using a pair of **thresholds** common to all the simulation.

This pair of **thresholds** is chosen so that:

- only **2.5%** of the simulated **LLs** is **bigger** than the **bias** previous computed
- only **2.5%** of the simulated **ULs** is **smaller** than the **bias** previous computed

①  
Pair of thresholds for linear case:

$$-2\Delta \ln \mathcal{L} = 3.4$$

$$-2\Delta \ln \mathcal{L} = 2.8$$

②  
Pair of thresholds for quadratic case:

$$-2\Delta \ln \mathcal{L} = 7.0$$

$$-2\Delta \ln \mathcal{L} = 4.4$$

# BACKUP SILDE 2

## We also investigated systematic effects:

- Possible change of spectral index of GRB190114C → Systematics < 5 %
- Cherenkov light collected by the telescopes overestimated by 15% in our analysis → Systematics ~ 18 % ( 29%) for subluminal (superluminal) case
