## Approach to scaling in axion string networks

*Monday, 5 July 2021 18:20 (20 minutes)*

In the QCD axion dark matter scenario with post-inflationary Peccei-Quinn symmetry breaking, the number density of axions, and hence the dark matter density, depends on the length of string per unit volume at cosmic time  $t$ , by convention written  $\zeta/t^2$ . The expectation has been that the dimensionless parameter  $\zeta$  tends to a constant  $\zeta_0$ , a feature of a string network known as scaling. It has recently been claimed that in larger numerical simulations  $\zeta$  shows a logarithmic increase with time. This case would result in a large enhancement of the string density at the QCD transition, and a substantial revision to the axion mass required for the axion to constitute all of the dark matter. With a set of new simulations of global strings we compare the standard scaling (constant- $\zeta$ ) model to the logarithmic growth. We also study the approach to scaling, through measuring the root-mean-square velocity  $v$  as well as the scaled mean string separation  $x$ . We find good evidence for a fixed point in the phase-space analysis in the variables  $(x, v)$ , providing a strong indication that standard scaling is taking place. We show that the approach to scaling can be well described by a two parameter velocity-one-scale (VOS) model, and show that the values of the parameters are insensitive to the initial state of the network. We conclude that the apparent corrections to  $\zeta$  are artifacts of the initial conditions, rather than a property of the scaling network.
