# **AMS 02: The Alpha Magnetic Spectrometer**

#### Composed by:

- TRD (transition radiation detector): distinguish proton /antiproton from electron/ positron
- TOF (Time of Flight Counters): determine the particle time of flight and charge
- Tracker: measure the particle rigidity and charge
- RICH (Ring Imaging Cherenkov counter): measure the particle charge and velocity
- ECAL (Electromagnetic Calorimeter): distinguish between protons and electrons or positrons.

#### Main objectives:

- search for Primordial Antimatter by direct detection of antinuclei
- search for indirect Dark Matter signals
- study of production, acceleration and propagation of Cosmic-Rays
- study of Solar Modulation

In orbit on the International Space Station since May 2011

## The AMS-02 Upgrade

- AMS02-LO, an upgrade which consist in adding a new silicon detection layer, called LO, above the existing L1 layer to increase the overall acceptance area.
- Composed of two layers of silicon sensors, where one layer is rotated 45 degrees relative to the other.
- The total area of the silicon sensors to be installed is ~ 8 m<sup>2</sup>. will increase by 300% the acceptance of the experiment.

To be installed in early 2026

### LADDER FOR AMS - LO

- To cover large areas without increasing the number of channels, the design must be based on "long" silicon sensor modules (called "ladders").
- Each ladder is composed of 8, 10, or 12 silicon sensors plus a frontend electronics board and a long flexible printed circuit board for mounting.
- Each silicon sensors with an area of 8x11 cm<sup>2</sup>, containing 1024 readout channels with a pitch of 110 μm.
- All channels of adjacent silicon sensors are connected in daisy chain to form a single sensor with longer strips.

#### **LADDER Electronics Front End Board**

- The board is equipped with 16 VA chips (IDE1140).
- Each two VA chips are connected to the same ADC.
- Only one digital interface
- The data compression (zero suppression) will be implemented in the FPGA itself

- Provides additional measurement points and constraints
- Extend the energy range of the positron flux measurement to ~ 2 TeV from the current ~ 1.5 TeV (1 TeV published in 2019) and reduce the uncertainties at least by a factor of two
- Extend the energy range of the electron flux measurement up to 3 TeV from the current ~ 2 TeV (1.4 TeV published in 2019) and reduce the uncertainties at least by a factor of about two
- Enable to provide a complete and accurate spectrum for all the 29 elements

Event display of an anti-<sup>4</sup>He data event. Y-Z is the bending plane. X-Z is the non-bending plane

Provides additional measurement points and constraints

- Extend the energy range of the positron flux measurement to ~ 2
  TeV from the current ~ 1.5 TeV (1
  TeV published in 2019) and reduce the uncertainties at least by a factor of two
- Extend the energy range of the electron flux measurement up to 3 TeV from the current ~ 2 TeV (1.4 TeV published in 2019) and reduce the uncertainties at least by a factor of about two
- Enable to provide a complete and accurate spectrum for all the 29 elements

Positron spectrum at highest energies for the current data (blue shading) and with the upgrade through 2030 (gold shading).

- Provides additional measurement points and constraints
- Extend the energy range of the positron flux measurement to ~ 2
  TeV from the current ~ 1.5 TeV (1
  TeV published in 2019) and reduce the uncertainties at least by a factor of two
- Extend the energy range of the electron flux measurement up to 3 TeV from the current ~ 2 TeV (1.4 TeV published in 2019) and reduce the uncertainties at least by a factor of about two
- Enable to provide a complete and accurate spectrum for all the 29 elements

Positron spectrum with the upgrade through 2030 (cyan points) together with a dark matter prediction (magenta curve) which includes cosmic ray collisions (green curve).

- Provides additional measurement points and constraints
- Extend the energy range of the positron flux measurement to ~
  2 TeV from the current ~ 1.5 TeV (1 TeV published in 2019) and reduce the uncertainties at least by a factor of two
- Extend the energy range of the electron flux measurement up to 3 TeV from the current ~ 2 TeV (1.4 TeV published in 2019) and reduce the uncertainties at least by a factor of about two
- Enable to provide a complete and accurate spectrum for all the 29 elements

Electron spectrum at high energies for current data (blue shading) and with the upgrade (gold shading).

- Provides additional measurement points and constraints
- Extend the energy range of the positron flux measurement to ~ 2 TeV from the current ~ 1.5 TeV (1 TeV published in 2019) and reduce the uncertainties at least by a factor of two
- Extend the energy range of the electron flux measurement up to 3 TeV from the current ~ 2 TeV (1.4 TeV published in 2019) and reduce the uncertainties at least by a factor of about two
- Enable to provide a complete and accurate spectrum for all the 29 elements

Origin of high energy electrons. the electron spectrum can be described by the sum of two power law components and a charge symmetric positron source term.

- Provides additional measurement points and constraints .
- Extend the energy range of the positron flux measurement to ~ 2 TeV from the current ~ 1.5 TeV (1 TeV published in 2019) and reduce the uncertainties at least by a factor of two
- Extend the energy range of the electron flux measurement up to 3 TeV from the current ~ 2 TeV (1.4 TeV published in 2019) and reduce the uncertainties at least by a factor of about two
- Enable to provide a complete and accurate spectrum for all the 29 elements

The 16 elements that AMS has published are marked in cyan. The 13 elements marked in white currently have limited statistics.

#### **Spatial Resolution**

LO Beam monitor (BM)

![](_page_12_Figure_2.jpeg)

![](_page_12_Figure_3.jpeg)

• The width (sigma) of the residual distribution can be expressed as the sum of two contributions, the intrinsic resolution of the sensor and the error in the fit prediction.

• 
$$\sigma_{RES,i} = \sqrt{\sigma_{fit,i}^2 + \sigma_{resolu,i}^2}$$
.

Mimimum Ionizing Particles peaks measured by Charge Detector (thanks to the INFN Florence HERD group)

![](_page_14_Picture_3.jpeg)

#### CONCLUSION

- The upgrade would provide improvement of a factor 3 of the AMS-02 acceptance
- The improved acceptance offers the possibility to reach enhanced accuracy in the cosmic rays measurements and possibly observe signals of new physics
- The production of the modules (ladders) is on-going and in few weeks all the modules will be ready for the final integration
- The modules are showing performances coherent to design and expectations:
  - the spatial resolution is around 12 micrometers
  - $\circ~$  the charge identification allow to identify nuclei up to nickel

Thank you for your attention.
